Executive summary and key findings

The state of California has enacted a variety of legislation establishing greenhouse gas (GHG) emissions reduction targets. Currently, the state has a net carbon sequestration target for the forest sector of 5 million metric tons (MMT) of carbon dioxide equivalent (CO₂e) annually until 2020, establishing a critical role for California's forests in meeting the state's targets. This data update was provided to inform several elements of the state's effort to meet GHG emissions reduction targets by compiling best-available data on GHG emissions, stock and flux from California's forest sector, identifying critical gaps in data, and suggesting strategies to reduce uncertainty in estimating the magnitude of stocks and flux within the forest sector.

This is the second data release in a series of annual Assembly Bill (AB) 1504 Forest Ecosystem and Harvested Wood Product (HWP) Carbon Inventory reports to the California Board of Forestry and Fire Protection (also referred to as the Board). This data release will not have a full report associated with it. For more detailed background on the inventory and methods, please refer to Christensen et al. 2017. Errors found after release of Christensen et al. 2017 are detailed in Christensen et al. 2018 and are also corrected in this data release.

The forest sector carbon data provided in this update comply with the Intergovernmental Panel on Climate Change Tier 3 good practice guidelines for carbon accounting (IPCC 2006, 2014) and is intended to assist the Board in evaluating and monitoring progress on meeting California's forest sector carbon sequestration target. This update can inform policy decision-making, but is not intended to be a complex policy assessment framework. Forest ecosystem carbon stocks and flux are established using direct measurements on forested plots throughout the state of California as part of the United States Department of Agriculture (USDA) Forest Service Forest Inventory and Analysis (FIA) program. Harvested wood product carbon stocks will be based on an IPCC Tier 3 production accounting approach and will be completed for the next full report within the year.

Based on the 2016 measurement cycle, California's forests remain net sinks, sequestering 31.8 MMT CO₂e per year, excluding net flux from soils, forest land conversions, non-CO₂ emissions from wildfires, or harvested wood products. This value is down slightly from the 2015 measurement cycle which estimated an average annual net sequestration rate of 33.6 MMT CO₂e per year. Most of the difference appears to be due to increased mortality, in addition to some decreases in growth rates that may be related to the recent drought. When comparing the 2015 and 2016 report tables 4.3/appendix B1, it is evident that the additional year of re-measured plots increased the statewide average mortality by approximately 1 MMT CO₂e per year and decreased the average growth by approximately 0.3 MMT CO₂e per year. However, changes in growth, removals, mortality and flux vary in each region, displaying different

patterns amongst each category. Additional work is being completed to assess these differences in more detail. After accounting for flux from soils, forest land conversions and non-CO₂ emissions from wildfires (excluding HWP), the estimated rate of carbon sequestration is 30.7 MMT CO₂e per year, down slightly from the 2015 measurement cycle which estimated 32.8 MMT CO₂e per year.

Carbon stocks are still just over 2 billion metric tons. However, in many forest types current stocking levels reflect over a century of fire suppression and may not represent stand densities that are resilient to disturbances common to California forests such as fire or pest outbreaks. Additionally, as the forests age in unharvested stands, growth rates slow. Older forests tend to store more carbon, but they might not accumulate new carbon as quickly as younger, fast-growing stands. Consequently, the stocks and flux represented in this report may not be sustainable into the future without forest management given the uncertainty in potential effects from climate change, the current level of forest disturbances from wildfire and pests, and aging of forests on federal lands. Forests provide many other services beyond carbon sequestration and storage, so there are many other considerations beyond forest carbon dynamics when developing management actions.

Key Findings:

The data presented in this report are based on the 2007-2016 FIA measurement cycle. Carbon stocks physically present in the forest are based on a 10-year average for the time-period of 2007-2016 and given in metric tons (MT) of carbon (C). The estimates of average annual carbon sequestration (i.e., net flux) is based on plots and trees initially measured between 2001 and 2006 then re-measured 10 years later between 2011 and 2016. Calculating flux based on actual growth, removals and mortality (i.e., the GRM approach) allows for annual reporting and is more robust than a simple stock-change approach. Stock information based on 2007-2016 FIA data or flux information based on plots initially measured between 2001-2006 and remeasured between 2011-2016 are also referred to as being based on the 2016 measurement cycle or the 2016 dataset. Results of carbon flux are given in metric tons (MT) of carbon dioxide equivalent (CO₂e). Carbon can be converted to CO₂e by multiplying by 3.667. Ranges in the text (i.e., ±) represent a 95% confidence interval (CI), while values in the tables report the sampling error (SE; CI = 1.96*SE). Confidence intervals around flux estimates tend to be slightly smaller than in the previous year's report because estimates are based on more plots (6/10ths of the full cycle compared to 5/10ths).

Forest land area:

- As of 2015 there are approximately 32 million acres of forest land across all ownerships.
- 16.5 million acres are classified as timberland with an additional 4.2 million acres of productive forest land in reserves.
- The federal government manages 58% of California's forest lands, with the remaining areas under state and local government (3.5%) or private management (39%) (Figure 2.4).
- Overall there was a net loss of forest land at the rate of 20.0 ± 9.8 thousand acres per year, primarily to developed land-uses (Table 4.8/E1). The confidence interval is high compared to the estimate because it is a relatively rare event at the scale of the inventory.
- Most of the forest land loss occurred on non-productive "other forest" (62%), followed by timberland (29%), with little change occurring on reserved lands (9%).
- Western oak woodlands cover the greatest area of all forest types at approximately 8.8 ± 0.37 million acres, followed by California mixed conifer at approximately 8.0 ± 0.34 million acres (Table 4.11; Appendix 2, Table A17).

Average net annual forest carbon dioxide sequestration - overview:

- Overall California forests are exceeding the 5 MMT CO₂e target rate of annual sequestration established by AB 1504.
- Based on plots initially measured between 2001-2006 and re-measured between 2011-2016, the average statewide rate of forest carbon sequestration is 31.8 ± 5.1 MMT CO₂e per year, excluding net CO₂e contributions from other sources such as forest soils, harvested wood products, forest land conversions and non-CO₂ GHG emissions from wildfire (Table 4.1, 4.3).
- Soil organic carbon is estimated to sequester 0.9 ± 0.9 MMT CO₂e per year (Table 4.1-4.3).
- Combined annual net emissions of non-CO₂ GHGs (methane and nitrous oxide) from wildfire is estimated to be 0.5 ± 0.1 MMT CO₂e per year (Table 4.2, 4.7).
- Changes in land-use between forest and non-forest land condition is estimated to have a net effect of emitting 1.6 ± 1.0 MMT CO₂e per year (Table 4.2, 4.9).
- Based on the 2016 measurement period, after accounting for these other CO₂ and greenhouse gas sources the statewide rate of carbon sequestration on all forest land is 30.7 ± 5.3 MMT CO₂e per year (Table 4.2), down slightly from the 2015 measurement cycle estimate of 32.8 ± 5.5 MMT CO₂e. This value currently excludes contributions from HWP pools.

Average net annual forest carbon dioxide sequestration – by pool:

- Growth on live trees, including foliage and live roots, makes up 88% of the annual CO₂e flux on all forest land at a net rate of about 27.9 ± 4.4 MMT CO₂e per year (Table 4.3).
- Standing dead trees, fallen down wood, and understory vegetation make up the remaining 12% of CO₂e flux (Table 4.3).
- Some portion of the 14.0 ± 2.6 MMT CO₂e flux (Table 4.3) associated with harvested wood is not immediately emitted as CO₂, but is stored as sequestered C. Information for these HWP pools will be provided in the next full inventory.

Average net annual forest carbon dioxide sequestration – by owner:

- The national forests provide the largest contribution, accounting for 36% of the statewide annual flux at a rate of 11.4 ± 2.7 MMT CO₂e per year (figure 4.1).
- Individual noncorporate forest land owners account for 33% of the statewide annual flux at a rate of 10.5 ± 1.6 MMT CO₂e per year (figure 4.1).
- Corporate forest land accounts for 16% of the statewide annual flux at a rate of 5.2 ± 3.6 MMT CO₂e per year (figure 4.1).
- State and local governments contribute 8% of the statewide annual flux at a rate of 2.6 ± 0.91 MMT CO₂e per year (figure 4.1).
- Other federal lands contribute 6% of the statewide annual flux at a rate of 2.0 ± 1.3 MMT CO₂e per year (figure 4.1).
- Only on reserved forest lands managed by the Forest Service is live tree growth not currently estimated to exceed carbon losses from the live tree pool due to tree mortality (Figure 4.4, Table 4.4).
- Annual gross growth per acre on live trees is currently exceeding all other carbon losses from the live tree pool due to mortality or harvest on unreserved timberland for all ownerships including lands managed by the Forest Service.
- The annual net rate of carbon sequestration per acre in the live tree pool is greatest on timberland owned by state and local government at 4.40 ± 2.10 metric tons of CO₂e per acre per year (Appendix 2, Table B12).
- The next highest annual net rate of carbon sequestration per acre in the live tree pool is on timberland owned by private individuals at 2.74 ± 0.44 metric tons of CO₂e per acre per year (Figure 4.4, Table 4.4).
- Trees growing on all ownerships across all of California's forests are sequestering carbon at a net rate of 0.73 ± 0.14 metric tons CO₂e per acre per year (Table 4.4).

Average net annual forest carbon dioxide sequestration – by region:

- The Sierra/Cascades region has the greatest net live tree CO₂e flux due to higher total annual growth in its forests relative to growth from other regions. This region also has the greatest rate of mortality but after accounting for harvest, live trees in the Sierra/Cascades region are still sequestering 7.8 ± 2.7 MMT CO₂e per year, more than any other region (figure 4.6). This is down slightly from the 2015 measurement period which estimated a rate of 8.7 ± 3.0 MMT CO₂e per year.
- The Southern Coastal Mountains and Deserts region is currently the only region where tree mortality is exceeding tree growth, resulting in a net carbon reduction of the live tree pool of 0.86 ± 0.54 MMT CO₂e per year (figure 4.6). Further analysis is needed to determine why this may be the case.

Carbon stocks for forest land remaining forest land (FF) by pool:

- Currently there are just over 2 billion metric tons of carbon stocks stored on forest land including forest soils across all ownerships in California (Table 4.12, figure 4.9, 4.10).
- Just over half of this stored carbon is found above ground in the live tree pool (including foliage) ($1,066 \pm 27$ MMT C, Table 4.12, figure 4.9).
- Forest soils store about a quarter of the stored carbon (506 ± 6.7 MMT C, Table 4.12, figure 4.9).
- Approximately 10% of the stored carbon is found aboveground in dead wood pools (205 ± 6.4 MMT C, Table 4.12, figure 4.9).
- These estimates exclude forest floor C as data was limited for this pool at this time. Initial estimates of forest floor C based on FIA measurements compiled in Gray et al. (2016) for National Forests in Oregon and Washington suggested that the forest floor made up 10% of non-soil forest C, which would translate to 7% of total C (143 MMT C) in Table 4.12 if the same ratio held. We suspect this number is too high and will go down with a better estimation approach.

Carbon stocks for forest land remaining forest land (FF) by owner:

- Approximately two-thirds of the carbon stocks in the state are found on public forest land (1,350 MMT C), with approximately 80% of that on National Forest System lands (1,077 MMT C) (Table 4.12, figure 4.8).
- Private corporate forest land contains approximately 16% of the state's carbon stocks (334 MMT C, Table 4.12, figure 4.8).
- Private noncorporate forest land contains approximately 18% of the state's carbon stocks (359 MMT C, Table 4.12, figure 4.8).

- Approximately 63% of the forest carbon stores are found on unreserved timberland (1,278 MMT C, Table 4.12, Figure 4.10).

Carbon stocks for forest land remaining forest land (FF) by region:

- Nearly half of California's carbon stocks in all carbon pools are found in a single region, the Sierra and Cascade Mountain Ranges. This region represents 48% of the forest land area and contains 957 MMT C (Table 4.19, figure 4.11).
- The next largest carbon store, the Klamath Interior and Coast Ranges region has about 60% the carbon stocks found in the Sierra and Cascades and just over a quarter of those found in the state at 580 MMT C (Table 4.17, figure 4.11).
- For each of these regions the dead tree and down woody material pools are each about 10% of the live tree carbon pool.

Carbon stocks for forest land remaining forest land (FF) by forest type:

- The California mixed conifer forest type contains the largest carbon stock compared to all other forest types, storing approximately 709 ± 33 MMT C (95% CI; Table 4.21, Figure 4.12).
- Western oak forests follow with 348 ± 18 MMT C (Table 4.20, figure 4.12).
- For most forest types the majority of carbon stores are found in live trees (Table 4.20, Figure 4.12).
- Most carbon stocks are found on unreserved timberland for most softwood forest types (Table 4.22, figure 4.13).
- The redwood forest type has the highest carbon density per acre (figure 4.14).
- Regional data by forest type is included in Appendix 1.

Comparison to the Forest Management Reference Level (FMRL):

- FIA's initial 10-year forest inventory in California installed from 2001 - 2010 is the FMRL basis (i.e., baseline) to evaluate relative changes in California forest carbon stocks between measurement periods.
- Stock-change comparisons to the FMRL cannot determine net flux until the entire 10-year re-measurement period is complete in 2020. The GRM method is used to estimate annual net flux.
- Comparison to the FMRL show that overall California's forest carbon stocks are increasing over time with minor annual variations (table 4.31).

Harvested Wood Product (HWP) carbon:

- Currently work to estimate HWP C is being completed through an agreement between CALFIRE, the USDA Forest Service Pacific Northwest Research Station (PNW), and the University of Montana Bureau of Business and Economic Research. From this work, a detailed IPCC Tier 3 inventory of the harvested wood product carbon pools will be conducted for the AB 1504 Forest Ecosystem and Harvested Wood Products carbon inventory expected to be released in late 2018.

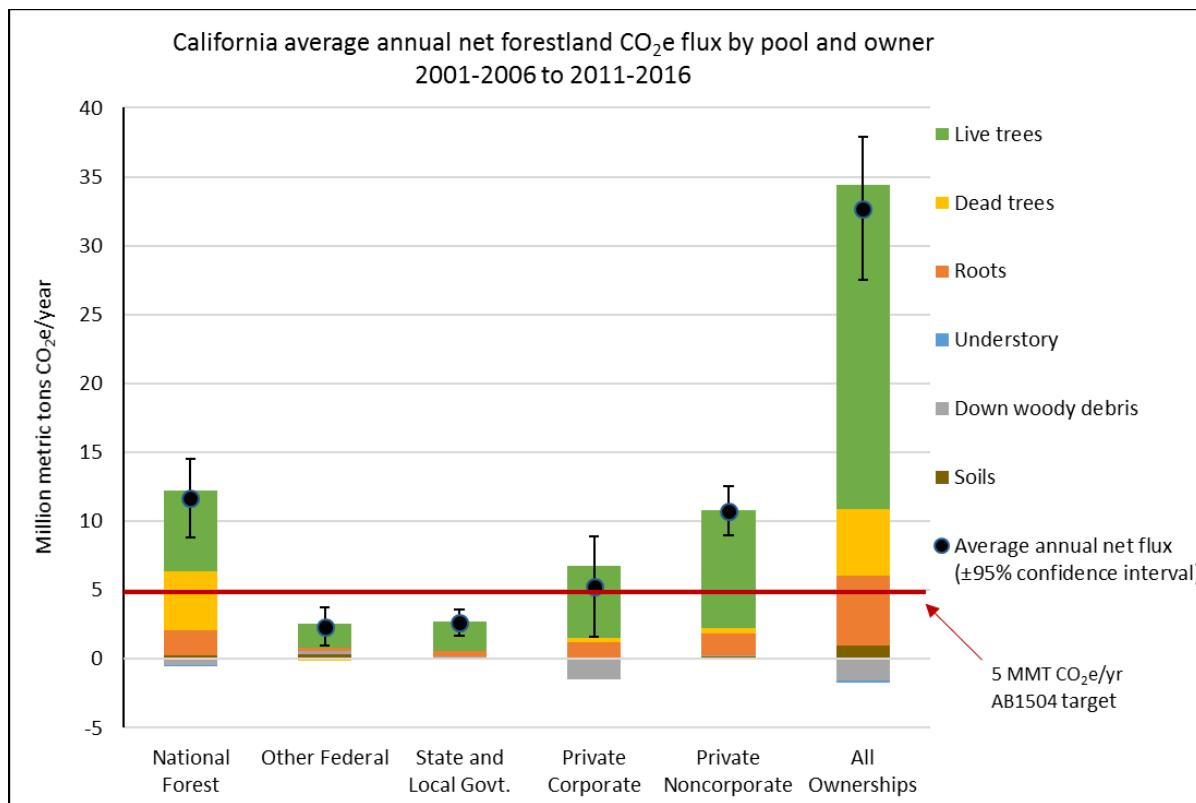

Figure 4.2. California average annual net forestland carbon flux by pool and ownership, 2001-2006 to 2011-2016 (MMT CO₂e/yr). Estimates exclude emissions from land-use changes (1.5 MMT CO₂e/yr) and non-CO₂ greenhouse gases (0.5 MMT CO₂e/yr). Roots includes belowground live and dead tree roots. Understory includes aboveground and belowground understory vegetation. Error bars represent the 95% confidence interval of estimated net flux. Figure derived from Table 4.3/Appendix 2, Table B1.

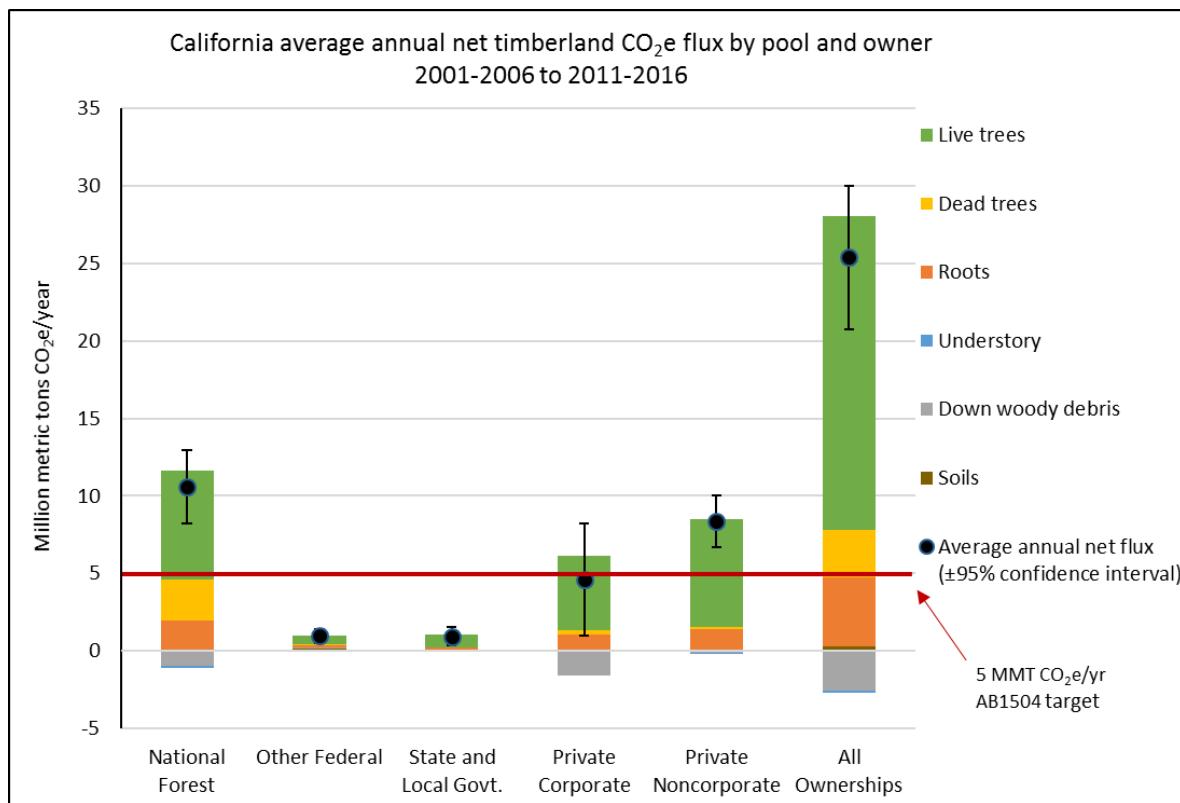

Figure 4.3. California average annual net timberland carbon flux by pool and ownership, 2001-2006 to 2011-2016 (MMT CO₂e/yr). Estimates exclude emissions from land-use changes (1.5 MMT CO₂e/yr) and non-CO₂ greenhouse gases (0.5 MMT CO₂e/yr). Roots includes belowground live and dead tree roots. Understory includes aboveground and belowground understory vegetation. Error bars represent the 95% confidence interval of estimated net flux.

California average annual net CO₂e flux per acre in the aboveground live tree pool from growth, mortality and harvest by ownership and land status
2001-2006 to 2011-2016

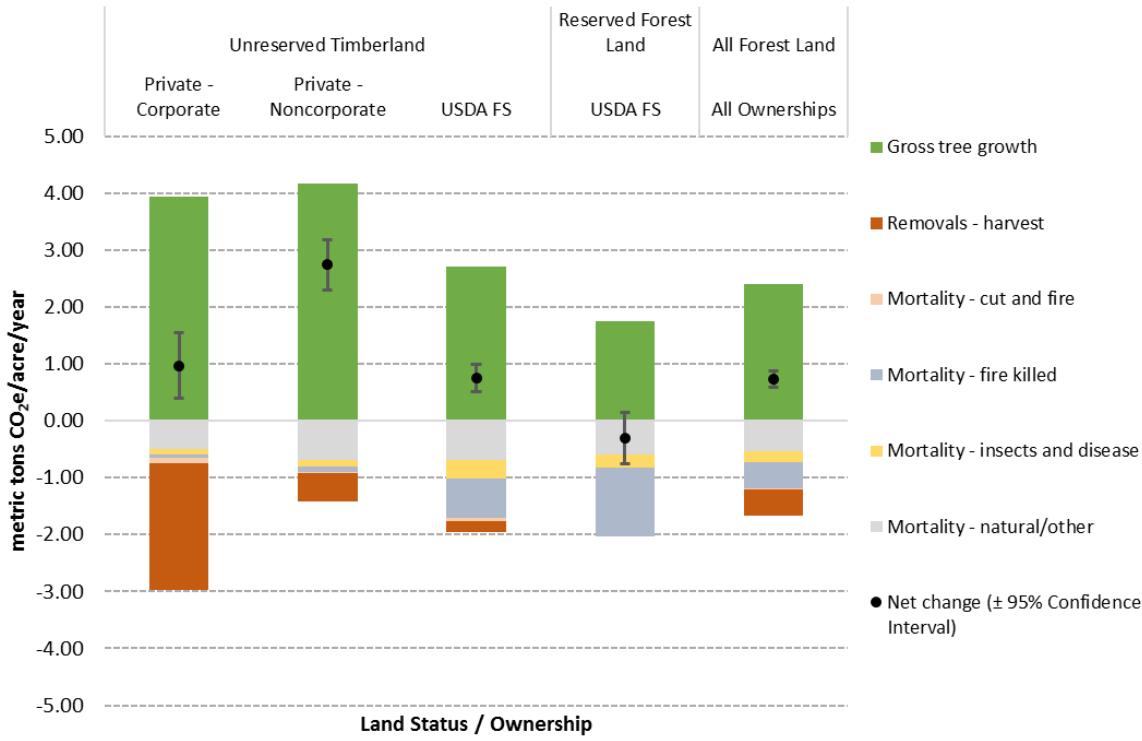

Figure 4.4. Average annual net CO₂e flux per acre in aboveground live tree carbon pool from growth, mortality and harvest by ownership and land status of California's forests (MT CO₂e/acre/year), 2001-2005 to 2011-2015. The “all ownerships” category includes all other state and federal agencies managing fewer overall acres of forest land in California. The error bars represent the 95% confidence interval of net change. Figure derived from Appendix 2, Table B12.

Appendix 2: 2007 - 2016 California FIA forest carbon inventory tables

Flux are based on plots initially measured between 2001-2006 and re-measured between 2011-2016.

Stocks are based on 10-year averages with the current reporting period being 2007-2016.
