

California Board of Forestry and Fire Protection Effectiveness Monitoring Committee (Project EMC-2023-002)

## Overview

#### Introduction

- Background
- Problem Statement
- Objectives

### Methodology

- Approach and Design
- Data and Analysis

#### Results So Far

- Key Findings
- Challenges and Limitations

## Next Steps

- Context and Problem Statement
- Objectives

## INIROLCIION

## Background

Lakes, rivers, and riparian zones in California's forests support biodiversity, provide critical water resources, and offer recreation opportunities, but recent wildfires have severely impacted these areas.

## **Objectives**

Assess fire history, current fire hazards, and vegetation recovery in CA's WLPZ areas, focusing on burn severity, vegetation changes over time, and the impact of forest management practices.

### Problem Statement

High-severity wildfires have damaged California's critical water networks and riparian zones, necessitating an assessment of how different management practices affect the resilience and recovery of these areas.

## Methodology

### Locate WLPZs

- 300' buffer for all waters
- Cal Hydro lines
- Streamflow model

### Fire History and Severity in WPZs

- CA-wide WLPZs + Fire
- Acres burned (1970-2023)
- Burn severity MTBS + RAVG (1984-2023)
- Dashboard (draft)

### Plumas County Case Study – PFVR

- Post Wildfire Vegetation Monitoring System
  - Landsat + GEE
- LandTrendr
  - NDVI

## Fire Hstory, Hazard, Veg by Ownership

Fire + Stream Classification+ THP type

### Statistical Analysis

- Assess trends in fire severity and vegetation cover
- Analyze influence of topography (aspect, slope, latitude) on trends
- Determine if management activities had an influence on trends

# **Flow Permanence Modeling**

Starting with flow accumulation derived from DEMs as a first step for determining where water is likely to gather — pointing to spots with a higher chance of sustained flow. An improvement over this method would be Topographic Wetness Index (TWI) which combines flow and slope to highlight areas with higher soil moisture, and a higher likelihood of supporting permanent or near-permanent streams.

If we stratify by soil types this could improve the predictive power of TWI, since things like soil permeability and water retention can strongly influence where water is held.

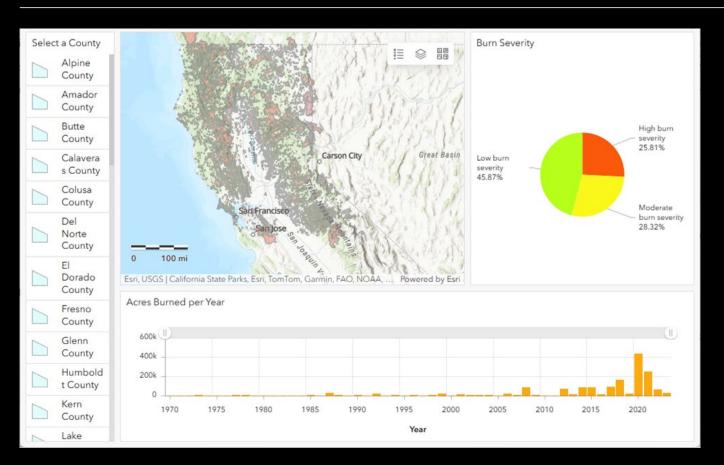

Other useful tools include NDVI (Normalized Difference Vegetation Index) to spot moisture-loving vegetation, climate data (rainfall and temperature) to account for seasonal changes, and land cover data for understanding what's going on in the watershed. On the more advanced end, the USGS PROSPER model offers a data-driven approach to predict stream permanence, and the HEC-HMS model goes even further by simulating streamflow in intricate water systems

## Draft Dashboard

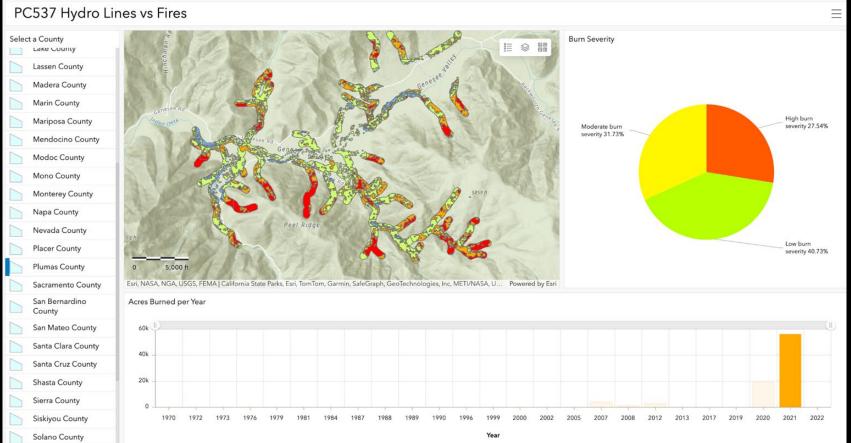

The dashboard can be used to dynamically explore the data.

## Draft Dashboard – Plumas County (2021)

#### What is LandTrendr?:

 It's a tool used in environmental monitoring to track how landscapes change over time using yearly composites of Landsat images

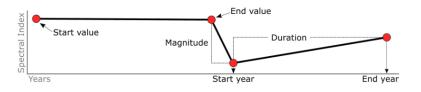

#### **How LandTrendr Works:**

- Looks at a time series of images to spot changes
- Segments the values per pixel through time, summarizing changes
- These segments allow LandTrendr to identify when the disturbance occurred, the magnitude, and duration of the disturbance

#### Applications:

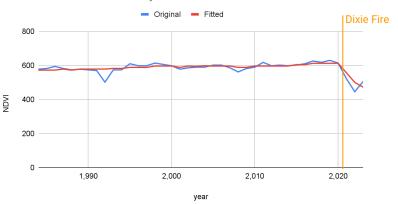

- Environmental monitoring, forest management, and conservation efforts
- By showing long-term changes, it provides detailed information on forest health

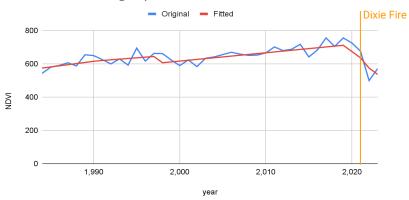

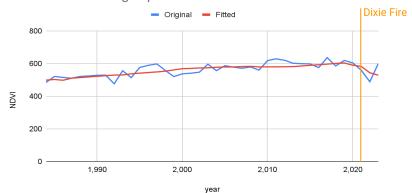

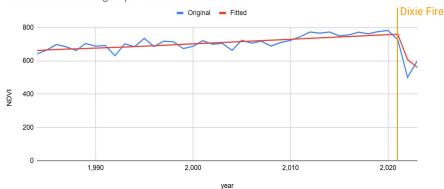

#### LandTrendr stream group 3 ITS

#### LandTrendr stream group 3 No treatment

LandTrendr stream group 3 Historic Harvest Area

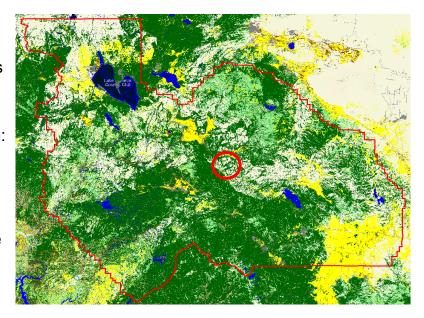

#### **Post Fire Vegetation Monitoring System (PFVMS):**

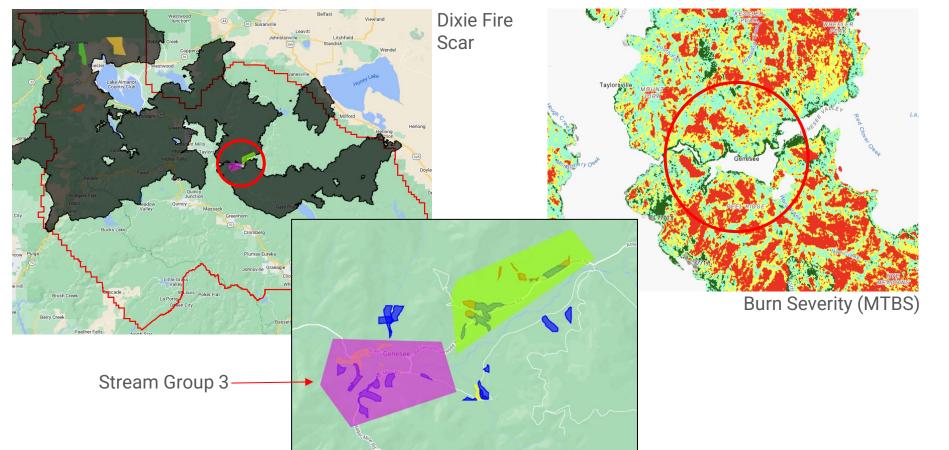

- Along with LandTrendr, we are analyzing trends in land cover changes using Google Earth Engine (GEE) and the PFVMS
- The PFVMS contains annual 30 meter Landsat composites of 8 land cover classes from 1984 to 2023

#### Assessing Watercourse and Lake Protection Zones (WLPZs):

- When we focus on specific zones of interest, like riparian areas, the PFVMS data helps identify where these areas have experienced positive or negative changes in vegetation cover and type
- Once we have identified the riparian areas, we can find the intersection of these areas with areas of known forest treatment
- These areas can then be split by the types of treatments that intersect with riparian areas and the location of these areas within the fire boundary
- From this, we can classify which treatments have led to improvements or degradation in biophysical conditions

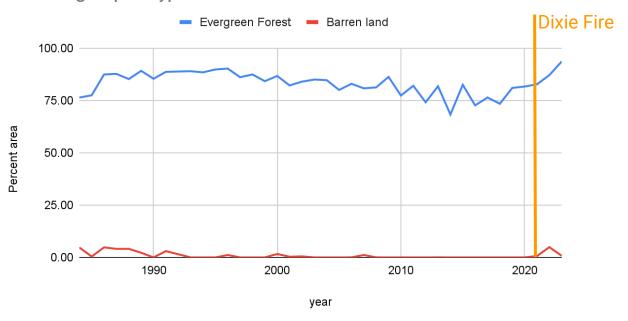

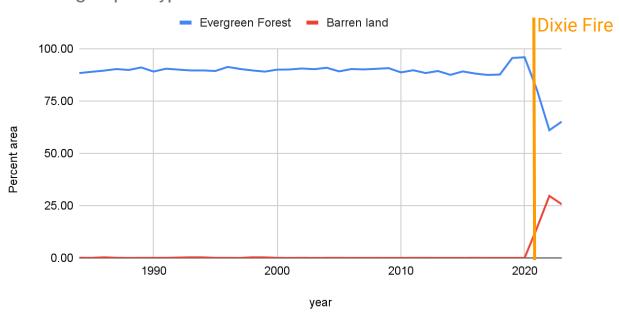

### Stream group 3 Type 1 - Historic Harvest Area

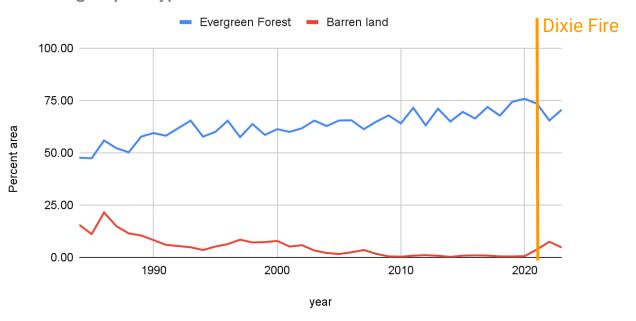

### Stream group 3 Type 2 - Historic Harvest Areas

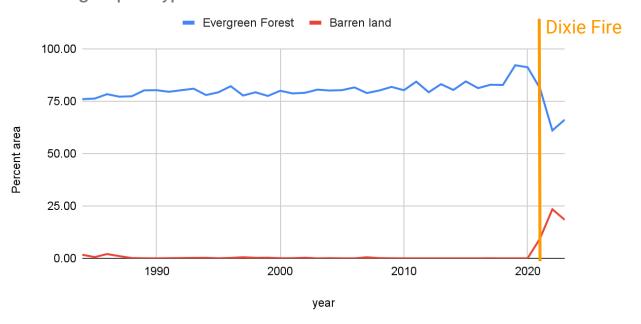

### Stream group 3 Type 1 - ITS

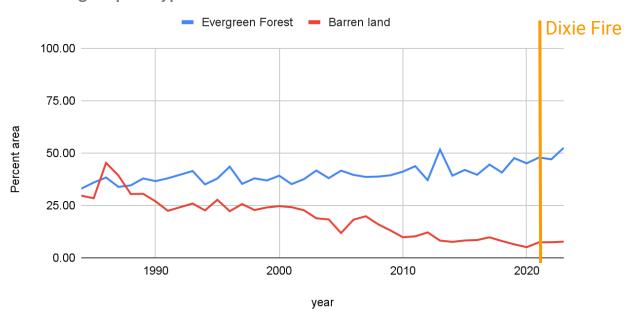

### Stream group 3 Type 2 - ITS

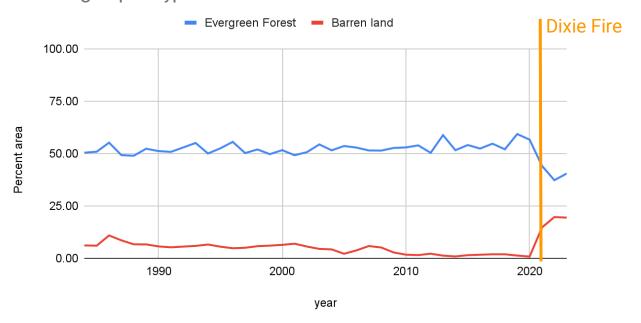

### Stream group 3 Type 1 - No treatment

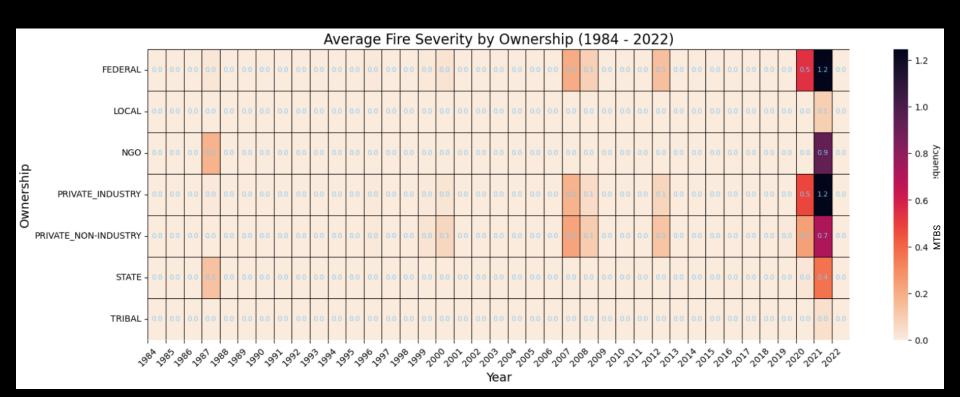

### Stream group 3 Type 2 - No treatment

## STATISTICALANALYSIS

## Results So Far

#### Locate WLPZs

- 300' buffer catches disturbance signals
- Differences between property type and stream classification

### Plumas County Case Study—PFVR

 Dixie fire signal varies by property type and WLPZ classification

### Fire Hstory and Severity in WPZs

- Historically, low severity fire dominates in WLPZs Statewide
- In 2020 435K acres of WLPZ burned – 34% high severity

## Statistical Analysis

- Federal and Private-Industrial lands highest fire severity in and out of WLPZs
- 2021 Fire severity decreases moving towards WLPZs
- 2020 Fire severity slightly increases moving towards
  WI P7s

## **Expand and Contextualize**

- Augment WLPZ dashboard data
  - Trend analysis
- Expand Plumas Co. Case Study
  - o additional stream groups
  - Additional fires

## Statistical Analysis

- Refining distance analysis
- Long Short-Term Memory Model
- Dr. Greg Fanslow

## Target/Visit Field Sites

- PFVM informed ground truthing
- UAV imagery
- 360° imagery
